We have a link to our project here: <https://github.com/maelm22/Model-based-Software-Development>

Since we are working in a game engine, there are a lot of files. The relevant ones for our DSL are located in *model-based-software/Scripts/Guard_states* (for the implementation) and *model-based-software/Scripts/State_machine* (for the general state machine builder). The example can be found in the script *Base.Gd* *model-based-software/Base.gd*.

Since we have written it in GDScript, executing requires the Godot engine which contains the compiler. We have verified that it works and checked with the instructor that it is okay. We have executed a simple state machine within a game scene containing a guard (controlled by the state machine) and a player (controlled by the player using WASD or arrow keys). The guard has two states: Patrol and Pursue. At the start of the game, the state is Patrol. When the player moves within the line of sight of the guard and the state is Patrol, its state changes to Pursue. If the guard is in Pursue and unable to see the player, the state changes back to Patrol. Each state has different behavior.

We used fluent API for the implementation technique. We are also working with some built-in methods within the game engine.

Yoganata Kristanto

I saw it worked the other day. that looked good!
